Nomenclature

Latin Symbols	Unit	Description
\mathbf{c}	m/s	Constant Velocity vector
c	m/s	Constant Velocity
f	$\text{kg s}^3/\text{m}^6$	Distribution function
E	J/m^3	Energy Density
H	m	Channel half-height
Ma	-	Mach Number
p	Pa	Pressure
R	$\text{J}/\text{kg}/\text{K}$	Specific gas Constant
Re	-	Reynolds Number
t	s	Time
T	K	Temperature
\mathbf{u}	m/s	Macroscopic Velocity Vector
u	m/s	Velocity in streamwise Direction
v	m/s	Velocity in wallnormal Direction
w	m/s	Velocity in spanwise Direction
\mathbf{x}	m	Vector of position
x	m	Coordinate in streamwise Direction
y	m	Coordinate in wallnormal Direction
z	m	Coordinate in spanwise Direction

Greek Symbols	Unit	Description
κ	-	Adiabatic Index
μ	kg/m/s	Dynamic Viscosity
ν	m ² /s	kinematic Viscosity
ξ	m/s	Microscopic Velocity
ρ	kg/m ³	Density
Ω	kgs ² /m ⁶	Collision Operator

Indices	Description
τ	Friction
b	Bulk
cp	Centerplane
f	Fluid
m	Mean
pwm	Plane-wise mean
rms	Root-mean square
s	Solid, Sound
w	Wall

Additional Symbols	Description
$\ \mathbf{a}\ $	Euclidian Norm
∇	Nabla Operator
Δ	Step
$\mathbf{a} \cdot \mathbf{b}$	Scalar Product, Matrix multiplication
a'	Fluctuation

Abbreviations	Description
BGK	Bhatnagar-Gross-Krook
DNS	Direct numerical Simulation
ERCOTAC	European Research Community On Flow, Turbulence And Combustion
LBM	Lattice-Boltzmann-Method
LBE	Lattice-Boltzmann Equation
LES	Large-Eddy Simulation
MRT	Multiple Relaxation Times Operator
NSE	Navier-Stokes-Equations
pdf	Particle-distribution Function
rms	Root mean square
WM-LES	Wall modelled Large-Eddy Simulation

3.1 Reinforcement Learning

3.1.1 Markov Decision Process

The mathematical formulation on which RL is based is the Markov Decision Process (MDP). Its two main components are the agent that given a state S_t takes an action A_t , and the environment, that responds to the action A_t with changing its state to S_{t+1} and giving feedback to the agent in form of a reward R_t . The interaction takes place at discrete time steps t and the sequence of state, action and reward is referred to as the trajectory. The dynamics of the MDP are described by the function p that is defined in (3.1). It defines the probability of the state s' with reward r occurring, given the state s and action a . Note that the following derivations will be constricted to finite MDPs, meaning that state and action space are discrete, however the concepts all are transferable to continuous action and state space.

$$p(s', r | s, a) \doteq \Pr(S_t = s', R_t = r | S_{t-1} = s, A_{t-1} = a) \quad (3.1)$$

For a process to be a Markov Decision Process, the p must only depend on s and a . Therefore s must include all information necessary to determine the future behaviour of the environment. This is not limited to information currently present in the environment, when thinking of this in terms of the wind farm problem at hand, the state could include data about wind speeds at the current time but also from time steps in the past. This approach allows to model virtually any interaction as a MDP, simply by including every bit of information from the beginning of time into the state. Obviously this is not feasible and therefore a careful choice of the information in the state is necessary.

The goal of the learning process is to maximize the sum of the rewards in the long run. Therefore a new quantity is defined, the return G_t that includes not only R_t but also the rewards received in future time steps. While in many applications of RL, the process naturally comes to an end, referred to as the terminal state S_T , in problems of continuous control this is not the case. Therefore the timeline is broken up into episodes. This allows for a finite computation of G_t . A typical formulation of G_t , referred to as a discounted return is given in (3.2). It includes a discount rate γ , that emphasizes rewards in the near future. If $\gamma = 0$, $G_t = R_t$, if $\gamma = 1$, the return is the sum of all future rewards. [1, p. 47- 57]

$$G_t \doteq R_t + \gamma R_{t+1} + \gamma^2 R_{t+2} + \gamma^3 R_{t+3} \dots = \sum_{t'=t}^T \gamma^{t'-t} R_{t'}, \quad \gamma \in [0, 1] \quad (3.2)$$

Now the goal of the learning process is defined, but not what to learn. There exist three possible answers to this question: a model of the environment, a value function or a policy. Also combinations of these components is possible. In the case of continuous control, most common approaches are model-free, meaning either learning a value function, a policy or both. Therefore model-based methods will not be discussed further and the reader is referred to the book by Sutton and Barto [1].

The policy π is the mapping from states to actions with a set of adjustable parameters. Under the policy π with its parameters set to θ , the probability of Action $A_t = a$ given a state $S_t = s$ is denoted as $\pi_\theta(a|s)$. The value function of a state s under a policy π_θ is denoted as $v_{\pi_\theta}(s)$ and is the expected return if the agent acts according to π_θ , starting from state s . Note that for convenience the parameters of π , θ , will be dropped. For MDPs it can be defined as (3.3).

$$v_\pi \doteq \mathbb{E}_\pi [G_t | S_t = s] = \mathbb{E}_\pi \left[\sum_{t'=t}^T \gamma^{t'-t} R_{t'} | S_t = s \right] \quad (3.3)$$

$$= \mathbb{E}_\pi [R_t + \gamma G_{t+1} | S_t = s] \quad (3.4)$$

$$= \sum_a \pi(a|s) \sum_{s'} \sum_r p(s', r | s, a) (r + \gamma \mathbb{E}_\pi [G_{t+1} | S_{t+1} = s']) \quad (3.5)$$

$$= \sum_a \pi(a|s) \sum_{s'} \sum_r p(s', r | s, a) (r + \gamma v_\pi(s')) \quad (3.6)$$

In the form of (3.6), the equation is referred to as the Bellmann equation and its unique solution is the value function v_π . Analogously, the action-value function is the expected reward of taking action a at state s under the policy π , denoted by $q_\pi(s, a)$. It is defined by (3.7).

$$q_\pi(s, a) \doteq \mathbb{E}_\pi [G_t | S_t = s, A_t = a] = \mathbb{E}_\pi \left[\sum_{t'=t}^T \gamma^{t'-t} R_{t'} | S_t = s, A_t = a \right] \quad (3.7)$$

$$(3.8)$$

When considering the optimal policy, which is the policy that yields the highest expected return for all states, the Bellman optimality equation can be written as (3.9), with v_* denoting the value function under the optimal policy.

$$v_*(s) = \max_a \sum_{s'} \sum_r p(s', r | s, a) (r + \gamma v_*(s')) \quad (3.9)$$

3.2 Policy Gradient Methods

3.3 backpropagation

3.4 ANN Design
